

3. Equilibria

Many reactions are reversible

All reversible reactions reach an **dynamic equilibrium** state.

Dynamic equilibrium occurs when **forward** and **backward** reactions are occurring at **equal rates**. The **concentrations** of reactants and products stays **constant** and the reaction is continuous.

We use the expression '**position of equilibrium**' to describe the composition of the equilibrium mixture.

If the position of equilibrium favours the reactants (also described as "towards the left") then the equilibrium mixture will contain mostly reactants.

Le Chatelier's Principle

We use Le Chatelier's principle to work out how changing external conditions such as temperature and pressure affect the position of equilibrium

Le Chatelier's principle states that if an external condition is changed the equilibrium will shift to oppose the change (and try to reverse it).

Effect of Temperature on equilibrium

If temperature is increased the **equilibrium will shift to oppose** this and move in the **endothermic** direction to try and reduce the temperature by absorbing heat.

And its reverse

If temperature is decreased the **equilibrium will shift to oppose** this and move in the **exothermic** direction to try and increase the temperature by giving out heat.

Typical Exam question: What effect would increasing temperature have on the yield of ammonia?

Exam level answer : must include bold points

If temperature is increased the **equilibrium will shift to oppose** this and move in the **endothermic, backwards** direction. The position of equilibrium will **shift towards the left**, giving a **lower yield of ammonia**.

Low temperatures may give a higher yield of product but will also result in slow rates of reaction. Often a compromise temperature is used that gives a reasonable yield and rate

Effect of Pressure on equilibrium

Increasing pressure will cause the equilibrium to shift towards the side with **fewer moles of gas to oppose the change** and thereby reduce the pressure.

And its reverse

Decreasing pressure will cause the equilibrium to shift towards the side with **more moles of gas to oppose the change** and thereby increase the pressure.

If the number of moles of gas is the same on both sides of the equation then changing pressure will have no effect on the position of equilibrium

Typical Exam question: What effect would increasing pressure have on the yield of methanol?

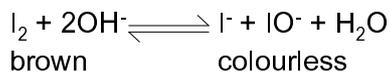

Exam level answer : must include bold points

If pressure is increased the **equilibrium will shift to oppose** this and move towards the side with **fewer moles of gas**. The position of equilibrium will **shift towards the right** because there are 3 moles of gas on the left but only 1 mole of gas on the right, giving a **higher yield of methanol**.

Increasing pressure may give a higher yield of product and will produce a faster rate. Industrially high pressures are expensive to produce (energy costs) and the equipment is expensive (to contain the high pressures)

Effect of Concentration on equilibrium

Increasing the concentration OH^- ions causes the **equilibrium to shift to oppose** this and move in the **forward** direction to remove OH^- ions. The position of equilibrium will **shift towards the right**, giving a **higher yield of I^- and IO^-** . (The colour would change from brown to colourless)

Adding H^+ ions reacts with the OH^- ions and reduces their concentration so the equilibrium shifts back to the left giving brown colour.

Effect of Catalysts on equilibrium

A catalyst has **no effect** on the position of equilibrium, but it will speed up the rate at which the equilibrium is achieved.

It does not effect the position of equilibrium because it speeds up the rates of the forward and backward reactions by the same amount.

Importance of equilibrium to industrial processes

You should be able to apply the above ideas to given reactions

Common examples

Learn the equations for the production of methanol and ethanol below

Haber process

T= 450°C, P= 200 – 1000 atm, catalyst = iron

Low temp gives good yield but slow rate:
compromise temp used

High pressure gives good yield and high rate:
too high a pressure would lead to too high energy costs to produce the pressure

Fe catalyst speeds up rate allowing lower temp to be used but has no effect on equilibrium

Contact process

T= 450°C, P= 10 atm, catalyst = V_2O_5

Low temp gives good yield but slow rate: compromise moderate temp used

High pressure gives slightly better yield and high rate: too high a pressure would lead to too high energy costs to produce the pressure

Catalyst speeds up rate allowing lower temp to be used but has no effect on equilibrium

Production of methanol from CO

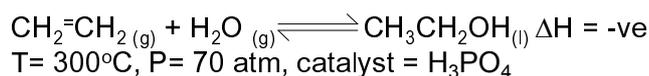

T= 400°C, P= 50 atm, catalyst = chromium and zinc oxides

Low temp gives good yield but slow rate:
compromise temp used

High pressure gives good yield and high rate:
too high a pressure would lead to too high energy costs to produce the pressure

catalyst speeds up rate allowing lower temp to be used but has no effect on equilibrium

Hydration of ethene to produce ethanol

T= 300°C, P= 70 atm, catalyst = H_3PO_4

Low temp gives good yield but slow rate:
compromise temp used

High pressure gives good yield and high rate: too high a pressure would lead to too high energy costs to produce the pressure

catalyst speeds up rate allowing lower temp to be used but has no effect on equilibrium

High pressure also leads to unwanted polymerisation of ethene

Both methanol and ethanol can be used as fuels

If the carbon monoxide used to make methanol in the above reaction was extracted from the atmosphere then it could be classed as carbon neutral

It would only be carbon neutral, however, if the energy required to carry out the reaction was not made by combustion of fossil fuels

The term carbon neutral refers to “an activity that has no net annual carbon (greenhouse gas) emissions to the atmosphere”
